### 1. Features

- Low dark current
- Auto black level calibration
- Two wire serial interface, 16-bit address and 8-bit data
- Support output format: YCbCr (4:2:2), RGB565, RGB555, RGB444, Raw, CCIR656, and REC also.
- Support image size: HD (1280 x 720), and any size from scaling down
- Lens shading correction
- Automatic control functions: Auto-Exposure control(AE), Auto-White Balance(AWB)
- Including: Sharpness, noise reduction, defect correction, gamma, color saturation adjust.
- Specical effects included.
- Embedded 1.5V regulator for core power
- Target module size: 8mm x 8mm
- Multi-Sensor Mode for 3D application.

## 2. Key Performance

Parameter		Value				
Array Size		1284 724				
	Digital	165 (±5%				
Power Supply	Analog	3.6V				
	I/O	1.7V ~ 3.6V				
Pixel Size		3.0 μm x 3.0 μm				
Image Area	, O	3852 μm x 2172 μm				
ADC Resolution	ELL	10 bits				
Shutter		Electronic Rolling Shutter				
Frame rate	640x360	60 fps				
Frame rate	HD (1280x720)	30 fps				
Color Filter Arrays		RGB Bayer pattern				
Maximum Data R	ate)	40Mp/s				
Maximum Clook	Rate	80MHz				
Power Consumpt	)) IOD	215 mW @ HD JPG				
1 Ower Consumpt	1011	Standby: < 10 uA				

## 3. General Description

The NT99141 is such a high performance image sensor that by incorporating a 1284H x 724V image array an on-chip 10 bits ADC, and embedded image signal processor all the required image signal processing functions including sharpness, noise reduction, defect correction, gamma, and color saturation adjust - are face fault supported, while its easy controllability and usability are maintained by the two-wire serial interface bus.

It is suitable for use in products such as cellular phones and PC cameras. **Block Diagram** Two-wire Row decoder SCLK **Timing** serial ( Pixel array interface control **SDATA** Column decoder Analog processing **JPEG RGB** YUV data output Digital image **ADC** Scaler processor Raw data output **Block Diagram**

## **Analog Gain Control**

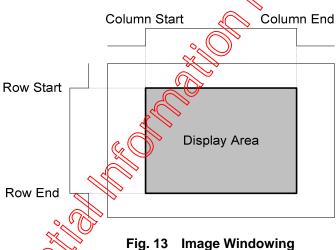

The amplifier gain can be programmed through the two-wire serial interface.

#### 10.4. 10-Bit ADC

The pixel output signal is digitized using the on-chip 10 bits ADC.

#### 10.5. Image Windowing

Users can program the window size through the two-wire serial interface bus. The (17) 141 output data is synchronized with the PCLK output. When HREF is HIGH, individual pixel value is outputted on the 10-bit data bus (D0 ~ D9) at each PCLK period. The pixel clock runs at a frequency rate determined by the sensor's master input clock (MCLK) and internal PLL configuration, where the rising edge of the DCLK signal occurs at one-half of each pixel clock period after the transitions in HREF, VSYNC, and DOW, (see the below: pixel data timing example / row timing and HREF, VSYNC signals)

Pixel Data Timing Example: (HREF default setting: active high)

### 11. Two-Wire Serial Interface Bus

User can control the register read/write through two-wire serial interface bus. The interface protocol uses a master/slave model in which a master controls one or more slave devices. The sensor acts as a slave device. The master device generates a clock MCLK that is an input to the sensor and used to synchronize data transfers. Data is transferred between master and slave on a bi-directional signal SDATA. SDATA must be pull up to VDDIO by a 1.5 k  $\Omega$  resistor.

Data transfer on the two-wire serial interface bus are performed by a sequence of low love protocol elements:

- a (repeated) start condition
- a slave address / data direction byte
- an (a no) acknowledge bit
- a message byte
- a stop condition

The bus is idle when both SCLK and SDATA are "high". Control of the bus is initiated with a start condition, and the bus is released with a stop condition. Only the master can generate the start and stop conditions.

#### Start condition

A start condition is defined as a high-to-fow transition on SDATA while SCLK is "high". At the end of a transfer, the master can generate a start condition without previously generating a stop condition; this is known as a "repeated start" or "restart" condition.

Stop condition

A stop condition is defined as a low-to-high transition on SDATA while SCLK is high.

Data transfer

Data is transferred serially, 8 bits at a time, with the MSB transmitted first. Each byte of data is followed by an acknowledge bit or a no-acknowledge bit. This data transfer mechanism is used for the slave address/data direction byte and for message bytes. One data bit is transferred during each SCLK clock period. SDATA can change when SCLK is "low" and must be stable while SCLK is "high".

• Data direction byte

Bits [7:1] of this byte represent the device slave address and bit [0] indicates the data transfer direction.

A "0" in bit [0] indicates a write, and a "1" indicates a read. The slave addresses used by the NT99141

2012/08/01 - 22 - Confidential

are 0x54 (write address) and 0x55 (read address).

#### Message byte

Message bytes are used for sending register addresses and register write data to the slave device and for retrieving register read data. The protocol used is outside the scope of the I2C specification and is defined as part of the MIPI and CSI.

#### Acknowledge bit

Each 8-bit data transfer is followed by an acknowledge bit or a no-acknowledge bit in the SCLK clock period following the data transfer. The transmitter (which is the master when writing, or the slave when reading) releases SDATA. The receiver indicates an acknowledge bit by driving SDATA "low". As for data transfers, SDATA can change when SCLK is "low" and must be stable while SCLK is "high".

#### No-acknowledge bit

The no-acknowledge bit is generated when the receive does not drive SDATA "low" during the SCLK clock period following a data transfer. A no-acknowledge bit is used to terminate a read sequence.

#### Typical sequence

A typical read or write sequence begins by the master generating a start condition on the bus. After the start condition, the master sends the 8-bit slave address/data direction byte. The last bit indicates whether the request is for a read or a write, where a "0" indicates a write and a "1" indicates a read. If the address matches the address of the slave device, the slave device acknowledges receipt of the address by generating an acknowledge bit on the bus.

If the request was a wite, the master then transfers the 16-bit register address to which the write should take place. This transfer takes place as two 8-bit sequences and the slave sends an acknowledge bit after each sequence to indicate that the byte has been received. The master then transfers the data as an 8-bit sequence; the slave sends an acknowledge bit at the end of the sequence. The master stops writing by generating a (re)start or stop condition.

If the equest was a read, the master sends the 8-bit write slave address/data direction byte and 16-bit register address, the same way as with a write request. The master then generates a (re)start condition and the 8-bit read slave address/data direction byte, and clocks out the register data, eight bits at a time. The master generates an acknowledge bit after each 8-bit transfer. The slave's internal register address is auto-incremented after every 8 bits are transferred. The data transfer is stopped when the

master sends a no-acknowledge bit.

## 11.1. Single Read from Random Location

This sequence (Fig. 25) starts with a dummy WRITE to the 16-bit address that is to be used for the READ. The master terminates the WRITE by generating a restart condition. The master then sends the 8 bit READ slave address/data direction byte and clocks out one byte of register data. The master terminates the READ by generating a noacknowledge bit followed by a stop condition. Fig. 25 shows how the internal register address maintained by the NT99141 is loaded and incremented as the sequence proceeds.

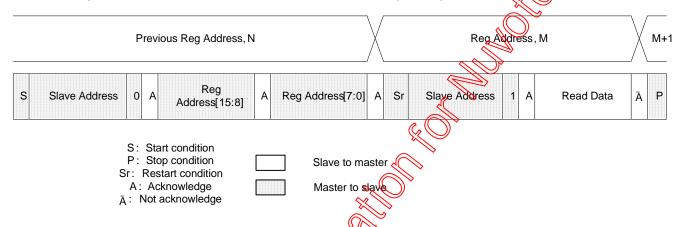

Fig. 25 Single read from random location

## 11.2. Single Read from Current Location

This sequence (see Fig. 26) performs a READ using the current value of the NT99141 internal register address. The master terminates the READ by generating a no-acknowledge bit followed by a stop condition. The figure shows two independent READ sequences.

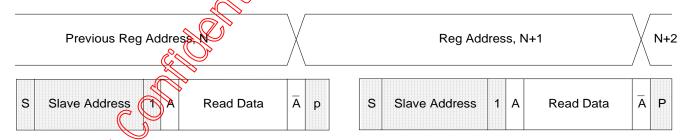

Fig. 26 Single read from current location

## 11.3. Sequential Read, Start from Random Location

This Sequence (Fig. 27) starts in the same way as the single READ from random location (Fig. 25). Instead of

2012/08/01 - 24 - Confidential

generating a no-acknowledge bit after the first byte of data has been transferred, the master generates at acknowledge bit and continues to perform byte READs until "L" bytes have been read. Previous Reg Address, N Reg Address, M M+1 Reg Slave Address 0 Reg Address[7:0] Sr Slave Address Read Data Ā S Address[15:8] M+1 M+2 M+L-2 Read Data Read Data Α Read Data Read Data Ā S

Fig. 27 Sequential read, start from random location

## 11.4. Sequential Read, Start from Current Location

This sequence (Fig. 28) starts in the same way as the single READ from current location (Fig. 26). Instead of generating a no-acknowledge bit after the first byte of data has been transferred, the master generates an acknowledge bit and continues to perform byte READs until "L" bytes have been read.

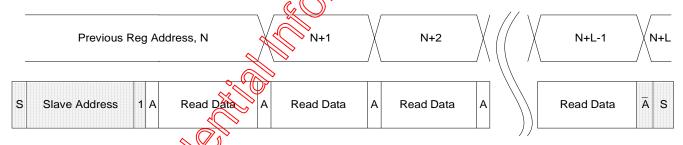

Fig 28 Sequential read, start from current location

## 11.5. Single Wite to Random Location

This sequence (Fig. 29) begins with the master generating a start condition. The slave address/data direction byte signals a WRITE and is followed by the HIGH then LOW bytes of the register address that is to be written. The master follows this with the byte of write data. The WRITE is terminated by the master generating a stop condition.

2012/08/01 - 25 - Confidential

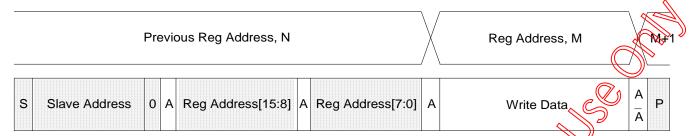

Fig. 29 Single write to random location

### 11.6. Sequential Write, Start at Random Location

This sequence (Fig. 30) starts in the same way as the single WRITE to random location (Fig. 29). Instead of generating a stop condition after the first byte of data has been transferred, the master continues to perform byte WRITEs until "L" bytes have been written. The WRITE is terminated by the master generating a stop condition.

### 16. Electrical Characteristics

## 16.1. Absolute Maximum Ratings

VDD Supply Voltage	-0.3	to	+2.0V
VDDIO / AVDD / AVDDPIX Supply Voltage	-0.3	to	+3.9V
Operating Ambient Temperature	-20°C	to	+70°C
Storage Temperature	-40°C	to	+85°C

#### Comment

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to this device. These are stress ratings only. Functional operation of this device at these or any other conditions above those indicated in the operational sections of this specification is not implied or intended. Exposure to the absolute maximum rating conditions for extended periods may affect device reliability.
